

LEVER DEVICE FOR CLAMPS OF A GARMENT-HANGER

Background of The Invention

The present invention relates to an improved lever device for clamps of a garment-hanger.

Garment-hangers of the so called type "with clamps" are already known and they include a rod with a hook and with two freely placed clamps in order to hold the hung cloth. Both of these two clamps include a couple of lever devices of the first order, pivoted on the rod and reciprocally joined and pre-loaded one against the other, in close configuration, by means of a pre-loaded "U" spring. Each lever device includes a first portion pressing on the fabric of the hung cloth (in opposition to the corresponding first portion of the other lever device of the pliers) and a second portion, on which the user's fingers act, during the opening of the clamp, acting against the spring power. On the inside of the first portion the surface pressing directly on the hung garment has special anti-slip features, in order to sustain the hold on the fabric.

At the present state of the art, different constructional solutions are known to be suitable for this purpose, comprising the application of a layer of soft rubber by molding or the use of removable tags embedded in the body of the lever device. All the known solutions have the drawback that they need complicated machines to realize the molding of the rubber on the lever device or to

10016354-102901

manufacture the tag, which, later, has to be placed on said element, which increases the final cost, which should be as low as possible, if we consider the kind of product.

Brief Summary of The Invention

An object of the present invention is to realize a completely automatic and inexpensive process to cover the inside part, that which is in touch with the fabric, of the lever device of a garment-hanger.

This object is achieved by providing strips of soft material, originally wound in a coil, which are at first placed, by means of a steady step movement, above the surface to be covered and, then, cut in sections, which are then joined to the surface below.

A first feature of the present invention is represented by the use of soft plastic materials such as, for example, polyurethane, neoprene, polyethylene and similar materials, which are not expensive and, up to now, have been used only to cover the rod and/or the ends of the arch structure of the rod garment-hangers. Velvet material can also be used.

A further feature of the present invention is represented by the fact that the welding of the strip sections on the surface of the lever device is achieved by means of a welding head, which carries out a linear welding connected only with the borders of said section, in such a way that part of the section, which is inside the welding cord, remains sufficiently soft, so as to raise the "sponge"

effect, which is typical of the material used.

A further feature of the present invention is represented by the fact that the welding, carried out by means of a welding resistance or laser head, is of the type called "in hot inclusion", which realizes only the fusion of the plastic support, represented by the lever device incorporating the material of the strip, which, with a higher melting-point, remains integral.

Brief Description of The Drawings

Further features of the present invention are more clearly shown by reference to the more detailed description, which is provided for the purpose of illustration and which is not intended to be limiting, of the steps of the process and of a possible embodiment of the lever device, by reference to the accompanying drawings, of which:

FIG. 1 is a perspective view of a garment-hanger with the lever devices of the present invention;

FIG. 2 is a perspective view of a lever device of the invention;

FIG. 3 is a perspective view of the lever of Fig. 2 showing the strip of soft material placed thereon;

FIG. 4 is a schematic elevational view of the plant of the present invention; and

FIG. 5 is a schematic view of the working step of the process of the present invention.

Detailed Description of The Invention

s shown in Fig. 1, the garment-hanger of the type called "with clamps" comprises a rod 1, with a hook, on which the two clamps 2, which hold the garment, are placed. Each clamp 2 comprises a pair of lever devices 3 of the first order, pivoted on the rod and reciprocally joined and pre-loaded one against the other, in close configuration, by means of a pre-loaded "U" spring (not shown). Each lever device 3 is divided into a first portion 4 pressing on the fabric of the hung garment (in opposition to the corresponding first portion of the other lever device of the clamp) and into a second portion 5, on which the user's fingers act during the opening of the clamp, acting against the spring tension.

As shown in Figs. 2 and 3, the inside part of the first portion 4 is covered by a strip 6 of plastic material, which is joined to the below support by means of a welding peripheral cord 7 which is placed substantially along the external profile of said welding strip. The portion 4, corresponding with the above strip 6, comprises a step 8, which allows to keep in a low position the welding cord 7, with reference to the contact zone of the hung garment and, moreover, to make softer the central zone of said strip 6.

As shown in Fig. 5, the strip 6 is placed, by means of known pulling devices (not shown), connected with the portion 4 and namely above the step 8. Afterwards the

welding head 10 is lowered and by means of the shaped electrode 13, at first, shapes the strips 6 on the step 8 and then realizes the peripheral welding cord 7.

Finally the lowering of the blade 14, projecting from the cutting group, divides the portion of the strip from the remaining band.

In order to make the process more productive it is possible to carry out the working described above simultaneously on more lever devices 3, placed in series; for example on the four elements which form the two clamps and which are molded together with the rod 1, which acts as support for the same.
